Expert Group- Freshwater Resources in Pakistan

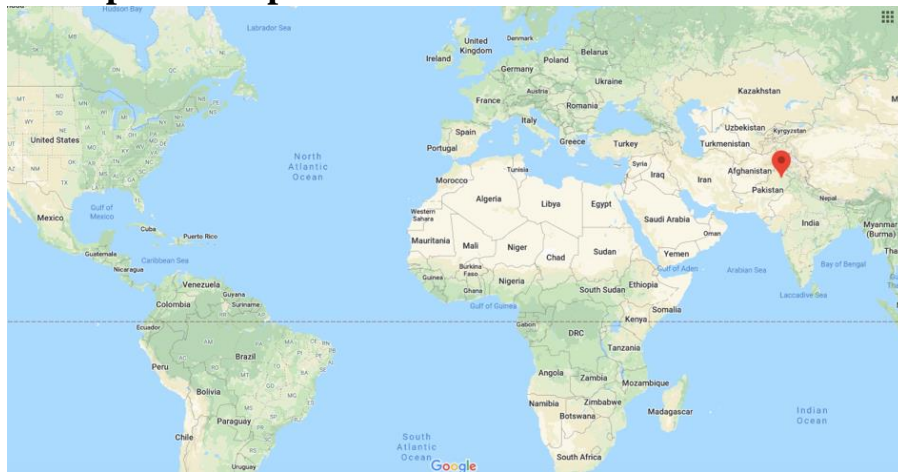

Figure 1: Location of Sargodha, Pakistan. Developed using [Google Maps](#)

When you turn on your faucet and get water, have you ever wondered where that water comes from? In the United States, most of our water is delivered through a public supplier such as the local county water department. These water suppliers get the water from either a groundwater source, such as a well, or from a surface-water resource, such as a river, lake, or reservoir. In some locations, especially rural communities, people may get their water from wells. In the U.S., the average person uses about 300 to 374 liters/80 to 100 gallons per day for indoor home uses. You can see about how much water you are using in your home through [this](#) form.

Today, Pakistan does not have enough freshwater resources to meet the needs of all the people who live there. It is known as a “water scarce” country, and freshwater availability is less than 0.001 liter/0.00026 gallon per person per day. There are many reasons for this freshwater scarcity. One of the reasons is that water management has not been a big focus of the government until recently. Agriculture is the biggest water user in Pakistan, and about 90% of the crops use irrigation, rather than relying on rainfall, to water their crops.

Pakistan’s main freshwater source for irrigation is the Indus Basin System. A “river basin” is land that the water in the area runs into, similar to a “watershed”. This river basin system irrigates over 45 million acres of farm land throughout the country. The Indus River is one of the longest rivers in Asia, and it runs from the far northern part of the country down to the Indian Ocean. The blue line shows us where the Indus river is located.

This figure is showing us which locations around the world are facing problems with not having enough freshwater resources. You can see that Pakistan falls into the dark red, meaning it is a country with extremely high “water stress”. That is another way of saying that there isn’t enough freshwater for people in that country to have access to enough freshwater to meet their needs. As you have probably noticed, some places in the world get a lot of precipitation, whereas other countries don’t get enough.

Some of the reasons that farmers are facing a shortage of freshwater for irrigation include dated farming methods, reduced water availability, dam silting, and an increasing population in the catchment areas. The rivers which feed into the Indus river basin have reduced the per person water availability from 5,000 cubic meters in 1951 to less than 1,000 cubic liters in 2010. At the present time, 85% of Pakistan's wheat production is dependent upon irrigated water.

The WRI (World Resources Institute) found that one of the best ways to reduce the use of valuable freshwater resources is to increase agricultural *efficiency*, meaning finding ways for farmers to plan ahead and be very careful with how much water they use. Farmers can reduce their use of freshwater on their crops by using “*precision watering*”. One way to do this is for engineers to develop technologies that improve farmers access to precipitation data. Dr. Hossain Faisal, a Civil & Environmental Engineering professor at University of Washington, is using data from one of NASA’s Earth observing satellite missions to do just that. You will learn more about him and his work.
